

**Amendments to the Specification:**

Please replace paragraph [0002] beginning at page 1, line 5, with the following rewritten paragraph:

[0002] A handle is occasionally used in various tools of our daily life, such as a mop, a besom etc[.]. Presently, the handles used are generally made of metal, wood, or bamboo. However, a metal handle has a high ~~cost~~ manufacturing cost and is easy to be corroded. A wood handle consumes much wood during manufacture and has a poor strength ~~is low in intension~~. A bamboo handle which is manufactured by natural bamboos generally has burl in its surface, thus it's asperate in surface and easy to split. Handles made of natural bamboo may also vary in diameter.

Please replace paragraph [0003] beginning at page 1, line 13, with the following rewritten paragraph:

[0003] The object of the present invention is to provide a solid ~~an infarete~~ handle formed by bonding several bamboo or wood chips, which not only keeps the excellent nature of the bamboo or wood handle, but also avoids the disadvantages of bamboo or wood handle, such as surface asperity, split, and poor strength ~~lower intension~~.

Please replace paragraph [0006] beginning at page 2, line 4, with the following rewritten paragraph:

[0006] In a further detailed technical solution of the present invention, it is provided with a bamboo or wood handle with a round cross section, which is formed by bonding a centric chip with four circumjacent chips, the centric chip having a quadrate cross section and the

circumjacent chips each having a curved cross section. The cross section of each circumjacent chip is comprised of a curved border, a short straight border and a long straight border. The short straight border with a length shorter than the long straight border is perpendicular to the long straight border. Each long straight border is bonded with the centric chip and each short straight border is bonded with the neighboring circumjacent chip at a portion where the long straight border of the circumjacent chip extends from the centric chip. The centric chip is formed by bonding two same small chips each having a rectangular ~~quadrate~~ cross section.

Please replace paragraph [0008] beginning at page 2, line 16, with the following rewritten paragraph:

[0008] 1. The handle according to the present invention is formed by bonding several bamboo or wood chips, thus it not only keeps the excellent nature of bamboo or wood, but also avoids the disadvantages of the bamboo or wood handle, such as surface asperity, split, and poor strength ~~lower intension~~.

Please replace paragraph [0009] beginning at page 2, line 20, with the following rewritten paragraph:

[0009] 2. The handle according to the present invention is formed by bonding centric chip with circumjacent chips, thus, it's well designed in configuration, economic in material use, and high in strength ~~intension~~.

Please replace paragraph [0014] beginning at page 3, line 2, with the following rewritten paragraph:

[0014] Referring to Fig. 1 and Fig. 2, a handle having a round cross section is formed by bonding a centric chip 1 with four circumjacent chips 2. The centric chip 1 has a quadrate cross section and the circumjacent chips 2 have curved cross sections. The centric chip 1 is formed by bonding two of the same small chips 11 each having a rectangular ~~quadrate~~ cross section. The cross section of each circumjacent chip 2 is comprised of a curved border 21, a short straight border 22 and a long straight border 23. The short straight border 22 with a length shorter than the long straight border 23 is perpendicular to the long straight border 23. Each long straight border 23 is bonded with the centric chip 1 and each short straight border 22 is bonded with the long straight border of the neighboring circumjacent chip 2 at a portion where the long straight border 23 extends from the centric chip 1.

Please replace paragraph [0015] beginning at page 3, line 13, with the following rewritten paragraph:

[0015] The handle according to the present invention is formed by bonding several bamboo or wood chips, thus, it not only keeps the excellent nature of bamboo or wood, but also avoids the disadvantages of the bamboo or wood handle, such as surface asperity, split, and poor strength ~~lower intension~~. Besides, the handle according to the present invention is formed by bonding centric chip with circumjacent chips, thus, it's well designed in configuration, economic in material use, and high in strength ~~intension~~.
